TRY CATCH

```
function sayHello(){
    try{
        console.log('Hi Simran');
    }
    catch(error) {
        console.log('opps! Error!')
    }
}
```

execute all the code inside of this block

@codewithsimran

The error that occured

If any error occurs inside try { } block, handle it inside the catch block

```
function sayHello() {
    try {
        console.log('Hi Simran')
        throw new Error('Damn error!')
        console.log('executed success')
    }
    catch(error) {
        console.log('Error', error)
    }
}
```

@codewithsimran

Scanned with CamScanner

> Hi Simran
Error Damn Error!

So it executes code inside of try { } block until it finds an error, and then moves to catch block. That's why executed success is not printed.

finally

@codewithSimran

```
function sayHello() {
    try {
    }
    catch (error) {
    }
    finally {
        console.log("Always printed")
    }

    console.log("outside try catch")
}
```

→ No matter what part of try and catch gets executed, whatever code we write inside finally will always get executed

↳ This piece of code will never get executed. (outside try catch)

Scanned with CamScanner

* Try catch can be used to handle synchronous code
* You can have nested try catch blocks
